# Course Project Proposal (Online)

## Speaker 1- Intro:

**Slide 1- QuickRouteOut is aimed to help people evacuate to safety using Dijkstra's Algorithm. Though the shortest path isn't always the quickest.**

**Slide 2 - Finding the quickest route: Other people's mapping software also use Dijkstra's Algorithm. The more people on the same road, the more chance for traffic to form. Instead, we are aiming for a way to find where most traffic occurs. This may cause the algorithm to find the next best route, which may find a longer, but quicker road.**

**Slide 3 - Finding the most accessible route takes a pre-downloaded 20 mile radius map, and uses the traffic data set to determine traffic, and the public building data set to also find food and shelter in that range.**

## Speaker 2:

**Slide 4 - How will it know if there is traffic, and whether there is shelter? The goal is to avoid most roads where traffic can form. And to find shelter, the data set finds the one closest to the 20 mile radius mark.**

**Slide 5 - This map shows how each data set serves its purpose, the Dijkstra's Algorithm mapping the quickest route, and the traffic data set**

**Slide 6 - Our first checkpoint will have a Flask application with the map ready to download locally, and display it, mapping the quickest route.**

**Slide 7- Our second checkpoint will use the traffic data set to estimate the least congested routes, and map the first better one.**

## Slide 8 - Thank you.
